

# Loop voltage - theoretical introduction

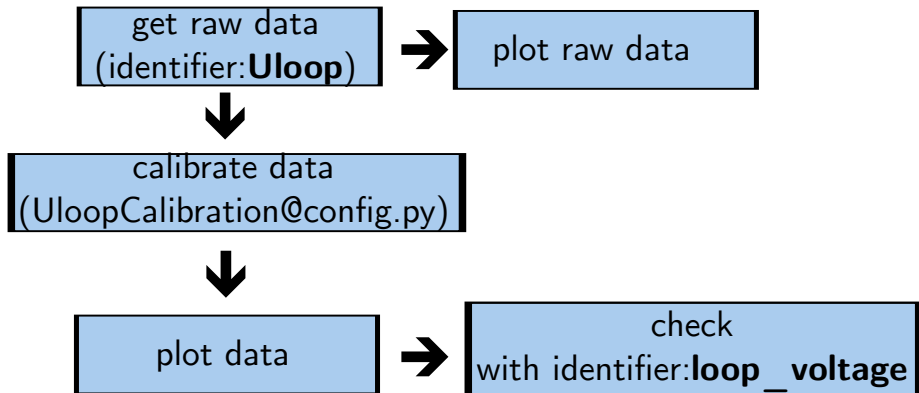

- Corresponds to the toroidal electric field  $E_t$  or time variance of  $\Psi$
- Voltage induced in a one loop of wire:  $U_l = \oint_l \mathbf{E}_t \cdot d\mathbf{l}$
- On a circular path:  $U_l = E_t 2\pi R$
- Kelvin-Stokes theorem transforms closed boundary curve integral  $\oint_l \mathbf{E}_t \cdot d\mathbf{l}$  into the "circulations of the fields":  $\iint_S \nabla \times \mathbf{E}_t \cdot d\mathbf{S}$
- From Faraday law  $\nabla \times \mathbf{E}_t = -\partial \mathbf{B} / \partial t$  the induced voltage  $U_l = -\iint_S \partial \mathbf{B} / \partial t \cdot d\mathbf{S} = -\partial / \partial t \iint_S \mathbf{B} \cdot d\mathbf{S} = -\dot{\Psi}$
